#### AERODYNAMIC STUDY

# CHARACTERISTICS OF AFT MOUNTED ALL-MOVING RECTANGULAR CONTROL SURFACES ON A SLENDER CRUCIFORM MODEL AT MACH NUMBERS FROM 0.6 TO 2.8

by

K. G. Winter Susan M. Mills

## SUMMARY

Ŧ

T

The wings are of delta planform, with aspect ratio of exposed pairs of panels 0.31, and total span of 2.5 times the diameter of the body, which is of fineness ratio 19. The rectangular controls, of span equal to that of the wings, and the chord 0.5 times the body diameter, are mounted with a half chord gap to the wing trailing edge. Loads are measured on one control in addition to overall loads. The tests cover an incidence range up to 22 degrees for 0 and 45 degrees roll and a complete roll range for incidences of 6, 12 and 20 degrees with elevator angles of 0, 10, 20 and 30 degrees. A brief survey of the flow in the region of the tail at M = 2.8 at an incidence of 20 degrees is included.

The results show that there are large variations with roll angle in both stabiliser effectiveness in pitch and elevator effectiveness. Aileron effectiveness is fairly constant. The rolling moment variation with roll angle on the complete model changes from being stable when one pair of wings is horizontal for all incidences at subsonic speeds and for low incidence at supersonic speeds, to being unstable for high incidence at supersonic speed. It is suggested that this effect may arise mainly from the interaction of the body vortices and of the vortices from the near horizontal wings with the wing on the leeside of the body.

#### 1 INTRODUCTION

î

The tests reported here were made to study the effectiveness of allmoving rectangular controls mounted fairly closely behind, and aligned with, the trailing edges of the wings of a slender cruciform model. Provision was made on the model to mount the controls in three positions with gaps of 0.05, 0.5 and 1.0 control chord between the control leading edges and wing trailing edges. The present tests refer to the middle one of the three positions. Treadgold and Pierce<sup>1</sup> have studied the variation in the behaviour of controls with change of position on somewhat similar models at a Mach number of 4.3. They found that controls very close behind the wing trailing edge had a marked non-linear variation in performance with both control angle and incidence which was alleviated as the gap was increased. In spite of the fact that the details of the results of Ref.1 must be dependent upon Mach number, it was considered that, on the basis of Ref.1, the present test should be restricted to one control position and that this should not be too close to the wing trailing edge.

The aim of the tests was to study control and stabiliser effectiveness as affected by model attitude both in incidence and roll angle and by Mach number. A parallel investigation, some preliminary results of which are given by Sadler<sup>2</sup>, studies the relative merits of various types of controls as applied to a monoplane model of larger span.

Because no measurements of control behaviour on the body alone were made, simple estimates for this condition are used as a criterion for effectiveness. Results of measurements on the model without controls are however included. As a further help in understanding the results, a brief survey of the flow in the region of the controls was made at a Mach number of 2.8 and an incidence of 20 degrees.

## 2 DESCRIPTION OF MODEL AND TESTS

The model with controls is shown in Fig.1. It is denoted as X  $B_5 W_8 A_1 C_{5_b}$ , where the symbols specify respectively that the model is cruciform, and the arrangement of the forebody, wings, afterbody and controls. The body is of length 16 diameters (d = 3.7 in) to the wing trailing edge including a nose length of 3 diameters, for which the shape is defined in Fig.1, and has a parallel afterbody length of 3 diameters. The wings have a total span of 2.5d, and the aspect ratio of the exposed pairs of wings is 0.3098; the thickness chord ratio is 1.39% at the root, and leading and trailing edges are chamfered at 15 degrees included angle normal to the edges. The controls, in line with the wings, are rectangular in planform of panel aspect ratio 1.5 and chord 0.5d. They are of simple double-wedge section with the maximum thickness of 10% chord at the 40% chord position which is also the hinge line position. The gap between the wing trailing edge and the control leading edge is 0.25d. The control root gap is about 0.004d or 0.008 times the control chord.

The model was mounted on a six component strain gauge balance, and one control panel (that set to starboard at zero roll angle and denoted by subscript y) was mounted on a balance. The balance, which rotated with the control, was gauged to measure force normal to the control surface, rolling moment about an axis in the plane of the control and hinge moment about an axis at 40% chord. The model base pressure was measured by means of a strain gauge pressure transducer connected to the balance cavity. Transition trips of 60 grade carborundum (0.01 in high) were provided on the body nose and on the wing and control leading edges.

Because the control angles could not be varied by remote operation, the test programme was chosen to minimise the number of control angle changes. It was assumed that there would be little interference between the controls, so that aileron power could be determined by measuring the rolling moment on the "live" panel only, and summing the results at intervals of 90 degrees in  $\lambda$  (roll angle) at a given total incidence  $\sigma$ . By varying two opposite controls as elevators, pitch or yaw control could be studied over the roll range. This could possibly have been done by varying one control only, but the pitching moment accuracy was marginal, and also the use of two controls avoids any uncertainty of the behaviour of the carry over of the lift to the body from one control compared with two. The basic programme was thus chosen to cover a variation in elevator angle  $\{\eta = \frac{1}{2} (\xi_y - \xi_{-y})\}$  giving pitching or yawing effectiveness, and measurements of loads on one panel (+y) to give aileron effectiveness.

All tests were run at a unit Reynolds number of about  $2 \times 10^6$  per foot  $(\text{Re}_{d} = 0.62 \times 10^6)$ . Details of the programme are given in Table 1.

## 3 PRESENTATION OF RESULTS

The overall loads are presented as aerodynamic coefficients  $(-C_z, C_m \text{ etc})$  referred to a set of right-handed axes fixed in the model, with origin 4d forward from the wing trailing edge, in which x is forward, and y is to starboard. The body cross-sectional area is used as reference area and the body

drameter as reference length. The axial force coefficient is corrected to zero base drag. Coefficients (-C'\_z, C'\_m etc) are also given, referred to axes in which x remains forward along the body but y' is normal to the plane containing the x axis and the wind vector, with x, y, z and x, y', z' coincident for zero roll angle ( $\lambda = 0$ ). Additionally lift and drag coefficients (C<sub>L</sub>, C<sub>D</sub>) are given in stability axes, where lift is measured normal to the plane containing the y axis and the wind vector, and drag is measured along the projection of the wind vector on the zx plane. The drag coefficient defined in this way is misleading at other than small values of roll angle in, for example, producing a change in drag coefficient between  $\lambda = 0$  and 90 degrees at given  $\sigma_{\bullet}$ 

The control loads are measured with respect to axes fixed in the 'live' control panel, and are expressed as coefficients  $(-C_z, C_m, C_\ell)$  in axes with origin at the intersection of the control hinge line and body centre-line, with  $y_p$  measured outwards along the hinge line, and  $z_p$  normal to the control plane, so that z and  $z_p$  are parallel only at zero control angle. Ignoring the chordwise force on the control, coefficients are also resolved to given coefficients  $(-C'_z, C'_p)$  referred to axes in which  $z'_p$  is parallel to z.

Other symbols used are defined in the list of symbols.

Complete sets of data are tabulated in Tables 2 and 3 but only results relevant to a brief analysis of the effectiveness of the controls both as stabilisers and as controls have been plotted.

The estimated relative accuracy of the data based on an assessment of the scatter of the raw measurements is given in Table 4 below for Mach numbers of 0.6 and 2.0. Also given are the maximum errors noted in nominally symmetrical arrangements where zero readings should be obtained.

s

Some of the differences between the two sets of figures, e.g. for rolling moment, are probably genuine in the sense that a completely symmetrical flow at high incidence on a slender body may well be unstable, and the least nonuniformity in model or approach flow will trigger an asymmetrical condition. The large errors in the panel loads are, however, mainly due to temperature sensitivity of the balance which was being used over a very small part of its load range. 3

## 4 CHARACTERISTICS AT $\lambda = 0$ AND 45 DEGREES

The basic results are plotted in Figs.2 to 9 and the analysis in Figs.10 to 17. The analysis is confined to the direct effectiveness of the controls, and only brief comments are made on other aspects of the results.

The main feature of the overall loads (in relation to control behaviour) not brought out in the analysis is the interaction between the control planes. The tests were not designed to study this, e.g. no information is obtainable on the interaction between ailerons and elevators. However, the yawing moment plots of Fig.5(a) show the presence of an appreciable interaction between pitching and yawing planes at M = 0.6 and  $\lambda = 45$  degrees, where the change in yawing moment due to elevator deflection is up to 20/2 of the pitching moment change. The load is in the sense of giving an incremental load on the yawing controls of the same sign as that due to incidence (or sideslip) but is not completely symmetrical with incidence. The effect diminishes as Mach number increases and is insignificant at M = 2.8.

The positions of the "live" control chordwise and spanwise centres of pressure, as well as normal force coefficient (resolved normal to the body) are shown in Figs.6 to 9. The chordwise centre of pressure position  $\bar{x}_p$  is referred to the hinge line in terms of body diameter d (which is twice the control chord), and is positive for positions forward of the hinge line. In the figures  $-\bar{x}_{n}$  has been plotted. The spanwise centre of pressure position,  $\bar{y}_{n}$ is in terms of body diameter, with the origin at the body centre-line. An attempt has been made to improve the accuracy of  $\bar{x}_p$  and  $\bar{y}_p$  by modifying the values for zero control angle as given in the tabulations to take account of non zero values of coefficients at zero incidence. The results, particularly for spanwise centre of pressure position, are still very scattered. At  $\lambda = 0$  and  $\eta = 0$  the chordwise centre of pressure at M = 0.6 and 0.8 is close to the quarter chord line  $(-\bar{x}_p = -0.075)$  and at supersonic speeds is close to the hinge line (40% chord,  $\bar{x}_{p} = 0$ ). Taking the control as an isolated panel, linear theory gives values of  $-\bar{x}_p$  ranging from 0.01 to 0.04 for M = 1.4 to 2.8 and the thickness effect 3 will bring the centre of pressure forward. At

large control angles the centre of pressure tends to the control centre of area  $(-\bar{x}_p = 0.05)$  at M = 0.6 and 0.8 but at supersonic speeds moves aft of this for large values of both control angle and incidence.

The spanwise panel control of area is at  $\bar{y}_p = 0.875$ . At zero control angle the centre of pressure is slightly inboard of this for incidence above about 10 degrees. At small incidence it moves outboard to values of  $\bar{y}_p$ around 1.0 or about two thirds exposed span. For the largest control angle it is near or just outboard of the centre of area, except at M = 2.8 where it is well outboard.

The panel normal force coefficients measured at  $\lambda = +45$  and -45 degrees have been plotted together (Fig.7), with the results at -45 degrees inverted. This treats the results at -45 degrees as being at +45 degrees with opposite signs of normal force, incidence and control angle and gives a fuller picture of the effect of control angle. Because of zero shifts in the data there is a discontinuity in the lines at zero control angle (as sketched in the plots).

Apart from regions where the normal force is small or passes through a zero, there is fair agreement between the chordwise centre of pressure positions at  $\lambda = 0$  and ±45 degrees. The spanwise centre of pressure position at  $\lambda = 45$  degrees agrees fairly well with that at  $\lambda = 0$  but tends to be further outboard at  $\lambda = -45$  degrees.

## 4.1 Stabiliser effectiveness, $\lambda = 0$ , 45 degrees

The contribution of the controls at zero control angle to the stability of the model can be assessed in three ways, firstly from the loads measured on the "live" control panel, secondly from the change in overall pitching moment produced by the addition of the controls and thirdly from the change in normal force. Following Pitts et al<sup>4</sup> an estimate of the load on a pair of panels on a body alone at zero control angle and incidence  $\alpha$  is

 $-C_{z_{p}} = C_{L_{\alpha T}} \frac{S_{C}}{S_{B}} K_{T(B)} \alpha ,$ 

the total normal force due to the addition of controls is

$$-\Delta C_{z} = C_{L_{\alpha T}} \frac{S_{C}}{S_{B}} (K_{T(B)} + K_{B(T)}) \alpha ,$$

and the additional pitching moment is

2

$$\Delta C_m = \ell_T \Delta C_z$$

where  $K_{T(B)}$  and  $K_{B(T)}$  are, respectively, the factors at zero control angle for the lift on the tail surfaces in the presence of the body, and the lift on the body due to the presence of the tail, with  $C_{L_{\alpha T}}$  the lift curve slope, based on their area, of the tail panels joined together, no distinction being made between normal force and lift. The tail arm,  $c_{T}$ , is measured in units of body diameter. Values of these estimates are summarised in Table 5, using slender body formulae for the interference factors, and linear theory for the net wing lift curve slope. The tail arm,  $\ell_{T}$ , has been taken as the distance from the moment reference point to the control hinge line. By dividing the respective measurements at an incidence  $\alpha$  by the estimates, values of effectiveness may be defined as follows

٠

$$k(p) = \frac{-C_{z_p}}{C_{L_{\alpha T}} \frac{S_C}{S_B} K_T(B) \alpha}$$

$$k(z) = \frac{-C_{z_{WBT}} - C_{z_{WB}}}{-C_{L_{\alpha T}} \frac{S_C}{S_B} (K_T(B) + K_B(T)) \alpha}$$

$$k = \frac{-C_{L_{\alpha T}} \frac{S_C}{S_B} (K_T(B) + K_B(T)) \alpha}{-C_{L_{\alpha T}} \frac{S_C}{S_B} \ell_T (K_T(B) + K_B(T)) \alpha}$$

where the subscripts W, B, T denote wing, body and controls respectively. Assuming the validity of the estimates, the various k will have a common value of  $\left(1 - \frac{\varepsilon_W}{\alpha}\right) \frac{q_e}{q_o}$ , where  $\varepsilon_W$  is the mean wing downwash across the control span and  $\frac{q_e}{q_o}$  is the ratio of kinetic pressure in the vicinity of the controls to its freestream value. Strictly there should also be included a term to account for any change of  $C_{L_{\alpha}}$  with change in local Mach number.

Figs.10 and 11 show for  $\lambda = 0$  and 45 degrees values of k(p), k(z) and k plotted against incidence. Also shown as the full line is  $\left(1 - \frac{\varepsilon_{V}}{\alpha}\right)$  derived from the incidence for zero normal force on the "live" control panel. For a

control angle  $\xi_{y}$  the panel normal force coefficient may be written

$$C_{z_{p}}^{i} = C_{L_{\alpha T}} \frac{S_{C}}{S_{B}} \{K_{T(B)} (\alpha - \epsilon_{W}) + k_{T(B)} \xi_{y}\} \frac{q_{\ell}}{q_{\infty}}$$

where  $k_{T(B)}$  is the slender body factor for the lift on the control panel in the presence of the body. Hence for C: = 0

$$\left(1 - \frac{\varepsilon_{W}}{\alpha}\right) = -\frac{\xi_{y}}{\alpha} \frac{k_{T(B)}}{K_{T(B)}}$$

There is considerable uncertainty in obtaining the value  $\xi_y$  for zero panel normal force because of the apparent zero errors. It has been assumed that the zero error in  $C_y^i$  for  $\xi_y = 0$  in Figs.6 and 7 applies also when  $\xi_y \neq 0$ .

Within the large scatter of the results there is reasonable correspondence between the three ways of obtaining effectiveness, with perhaps a tendency for k (from pitching moment) to be larger at large incidence than k(p) (from the panel load). The overall normal force gives very scattered results due to lack of accuracy. It is not used in subsequent determinations of effectiveness. The data is clearly not of good enough quality to offer any comment on the relative magnitudes of the interference factors used. The effectiveness is always small varying from less than 0.2 at small incidence at subsonic speeds to about 0.5 at high incidence and supersonic speeds. It is worth noting that at subsonic speed, the effective incidence of the controls at 20 degrees incidence of the body is only some 4 to 5 degrees and hence there is no indication of any stall for  $\xi_v = 0$  in Figs.6(a), (b) and 7(a), (b).

7

The results at  $\lambda = 0$  and 45 degrees are fairly similar with a tendency for the values at  $\lambda = 45$  to be higher at incidences of about 10 degrees but to fall off at higher incidence. The two panels concerned at  $\lambda = 45$  are operating in different conditions, and the correspondence with  $\lambda = 0$  is obtained only as an average of the two panels. The windward panel is in fact much more effective than at  $\lambda = 0$  and the leeward panel much less, as can be seen from Fig.27.

Referring to Fig.10 ( $\lambda = 0$ ) at the lower Mach numbers the effectiveness tends towards a pure downwash effect at large incidence, assuming that nonlinearities in lift curve are not significant because of the small effective incidence. At smaller incidence the effectiveness is well below that attributable only to downwash. For example at M = 1.4 and 5 degrees incidence a kinetic pressure of only about half freestream is implied. The effect of the wing flow field is thus important in more than reducing local incidence at the controls but also in producing reduction of local kinetic pressure. 32

.

One object of the extensive programme of which this experiment forms a part was to study how far missile shapes can be obtained in which the characteristics are independent of Mach number. It has been shown in Ref.<sup>1</sup> that at a Mach number of 4.3 local conditions at the wing trailing edge, considered two-dimensionally, play a dominant part in the behaviour of controls close to the trailing edge, and thus there might be expected to be a dependence of the flow pattern over the controls at a given incidence upon Mach number, at any rate for high supersonic speeds.

An attempt to assess how far this dependence can be seen in the present experiments has been made. It might be expected that, if the downwash pattern at a given incidence does not change with Mach number, the mean downwash over the controls would simply be proportional to the wing load producing the downwash; and, therefore, that the stabiliser effectiveness at a given incidence will be linearly related to the wing load with a value of unity for zero wing load. The load on one wing panel of a special version of this model has recently been measured by Ogle<sup>5</sup>, and Fig.12 shows the stabiliser effectiveness at zero roll and 20 degrees incidence plotted against a wing panel normal force coefficient. It can be seen that the values of k lie close to a straight line passing through unity for zero wing load but that, possibly the downwash varies more steeply. There is thus little evidence from Fig.12 to show a dependence of flow pattern upon Mach number within the range of these tests.

Sohlieren photographs in Fig.13 show marked changes in vortex pattern with change of Mach number. The photographs cover the Mach number range for incidences of  $\pm 20$  degrees with a control angle of 30 degrees. A possible interpretation of the photographs may be as follows. At the lower Mach numbers the body vortices are weaker and the wing vortices stronger than at high Mach numbers. The body vortices at lower Mach numbers are therefore closer to the body, and are pushed even closer to the body by the downwash from wing vortices. As Mach number increases, the situation progressively reverses, until the body vortices dominate and the upwash from them sweeps the wing vortices away from the body. There is thus a progressive increase of distance from the body of both wing and body vortices with increase of Mach number.

Because of the suggestions of Ref.1 a brief survey of the flow in the region of the controls was made at  $\alpha = 20$  degrees and M = 2.8 in a plane normal to the body axis, and situated at about 0.74 control chord. The crossflow directions measured relative to the body are shown in Fig. 14. The measurements were made along two circular arcs at radii from the body centreline of 0.81d and 1.08d. The lengths of the arrows are proportional to the crossflow angles and are not strictly crossflow vectors. The "full" arrows are the directions as measured. Now the effectiveness as shown in Fig. 10 is intended to exclude the effect of the body by using as datum estimates which include body effects. The estimates use slender body interference factors, and the corresponding datum for the flow field has been taken to be the crossflow past a cylindrical body in incompressible flow (even though the crossflow Mach number is 0,82). The directions corrected to this datum are shown by the broken arrows. On the line z = 0 the incidence is between 0.8 and 0.9 times the freestream incidence. The fields of the wing and body vortices, which are shown in the schlieren photograph to be at values of z/d of about -2.2 and -2.6, confuse the measurements for values of -z/d > 0.4 which is also roughly where the wing trailing shock intercepts the survey plane.

The local incidence is shown in more detail in Fig. 15 where the measurements are compared with a two-dimensional flow picture. The simple assumption has been made that the flow approaching the wing trailing edge is that obtained by isentropic expansion or compression from the freestream direction. At the trailing edge the flow on the lower surface traverses two expansion fans and that on the upper surface an expansion fan and a shock wave. Equilibrium between the two fields results in a small upwasn  $(\alpha_{local}/\alpha = 1.07)$ at the dividing streamline. There is a further interaction on the upper surface between the expansion fan and the shock wave, which has not been calculated in detail, and which may not happen in practice, because of flow separation over the rear of the upper surface. For the simple inviscid flow model taken, quantitative agreement would not be expected; qualitatively the model is well confirmed by the experiment, the results of which are plotted against height regardless of spanwise position. It should be noted that the traverse at the larger radius passes through the tip Mach cone (based on freestream Mach number) for small z/d. The local incidence at the control position, as a fraction of freestream, is reduced, presumably by wing and body vortices, to a value of about 0.8 compared with an estimate of 1.07 and compared with that derived from the control loads of about 0.6. The pitot pressure as a fraction of that in the freestream is also shown in Fig. 15. (The derivation

of local Mach number from the experiments was not of sufficient accuracy to make its determination and that of local total pressure meaningful.) The qualitative agreement with the simple estimate again confirms the general character of the assumed flow model. It may be concluded, for control surfaces close to a wing trailing edge, that local details of the flow which are Mach number dependent will play a part in determining their effectiveness. The importance of the local flow field will increase with Mach number and the correlation of Fig.12 may be expected not to be capable of extension to higher Mach numbers.

٠

## 4.2 Elevator effectiveness, $\lambda = 0$ , 45 degrees

The effectiveness at  $\lambda = 0$  and 45 degrees is shown in Figs.16 and 17 where  $k_{\eta}$  is derived from the change in pitching moment, and  $k_{\eta}(p)$  from the change in panel normal force, due to change in elevator angle. The changes of angle are taken from 0 to 10, 20 and 30 degrees, and the presentation thus masks to some extent the loss of effectiveness which occurs subsonically with increase of angle. To obtain a common basis for comparison the measured changes are again given as fractions of simple estimates for controls on a body without wings. The details of the estimates are listed in Table 5. At supersonic speeds there is good agreement between  $k_{\eta}$  and  $k_{\eta}(p)$  suggesting again that the relative values of the interference factors are adequately estimated, but  $k_{\eta}$  tends to be higher than  $k_{\eta}(p)$  at large incidence and large elevator angle at subsonic speeds. The effectiveness for zero incidence and 10 degrees control angle at  $\lambda = 0$  ranges from about 0.7 at M = 0.6, through a minimum of 0.6 at M = 1.4, to between 0.7 and 0.9 at the higher Mach numbers and is not too inconsistent with the kinetic pressure ratio which might be deduced from Fig.10.

The behaviour at  $\lambda = 45$  degrees (Fig. 17) is generally similar to that at  $\lambda = 0$  (Fig. 16) and there is fair agreement at zero incidence where the two sets are equivalent. The subsequent discussion is therefore limited to the results at  $\lambda = 0$ .

At M = 0.6 and 0.8 for small control angle and small incidence the effectiveness is slightly greater at positive incidence than at negative incidence but falls off at high positive incidence and increases rapidly for large negative incidence. At large control angles the variation with incidence and control angle reflects the peculiar behaviour of the panel normal force (Figs.6(a), (b)). Taking the variation of C at +20 degrees incidence with change of control angle there is apparently a stall for control angle above 20 degrees, with a maximum value of C of 0.43, which corresponds roughly to a coefficient based

on its area of about 0.9. This value\* is probably not far from the maximum lift coefficient for an unswept aerofoil with sharp leading edge at the same Reynolds number in a free airstream. (Various measurements of C, range from about 0.7 for large aspect ratio to about 1.3 for unit aspect ratio, with the stalling angle varying from about 7 degrees to over 30 degrees.) At smaller values of model incidence the panel normal force continues to reach a maximum for control angles above 20 degrees but the maximum depends upon the incidence. The explanation of this behaviour may lie in a complex interaction between the control surface, the wing wake and the body boundary layer. Because of the large wing downwash angles, the undisturbed wing wake would pass over some part of the control when set at a large angle. At negative incidence (and large positive control angle) the undisturbed wake would impinge on the rear part of the control. The circulation round the control might then bring the wake forward so that the control is more deeply immersed in the wake and might even create a large separation region on the body. As the incidence is increased positively the wake will move further forward along the control chord, and might eventually be swept over the control leading edge, alleviating the separation, and allowing the control normal force to increase with increasing incidence. Despite this behaviour at negative incidence the effectiveness is greater than at large positive incidence.

Because the flow is masked by the body the schlieren photographs of Fig.13 are not very helpful. However at M = 0.8 there is an interesting difference between positive and negative incidence. At +20 degrees incidence there are indications of disturbances in the vortex which look rather like the flow from an underexpanded jet. The same phenomenon appears on photographs without controls and one might guess that it is associated with vortex breakdown since the axial flow along the vortex core is likely to be supersonic. At negative incidence the disturbances are absent.

At supersonic speeds up to M = 2 the effectiveness is greater at negative incidence than at positive incidence, presumably because the wing wake passes beneath the control leading edge so that the control is immersed in the flow on the windward side of the body. Neglecting any shock losses, compression of the flow over the controls at supersonic speeds should increase the normal force because of an increase in both local lift curve slope and local kinetic pressure. At the higher two Mach numbers, because of the increasing influence of local conditions, it may be surmised that the wing wake is well clear of the controls for small control angles, so that the

• It might be noted that it is exceeded at other roll angles (Fig.23(a).

Ξ

Ξ

control always operates in the windward side flow, and is not greatly affected by the sign of the incidence. The effect of the wing wake as it passes over the controls at near zero incidence gives a sharp drop in effectiveness and becomes increasingly marked with increase of M. (

#### 5 VARIATION OF CHARACTERISTICS WITH ROLL ANGLE

The loads at three values of total incidence  $\sigma$  of about 6, 12 and 20 degrees are plotted against  $\lambda$  in Figs.18 to 25. The overall loads are given only in model axes since these are more directly related to the control functions. Data in other axes are given in Tables 2 and 3.

Because of the increased appreciation of the behaviour given by the control panel loads, some comments are made on the overall loads. The first point of interest is the non monotonic variation of normal force at 20 degrees total incidence in the regions of  $\lambda = \pm 90$  degrees (Fig.18) for M of 0.6, 1.4 and 2.0. This is also shown by the sideforce variation through  $\lambda = 0$  and 180 degrees (Fig.20). There is no reason to expect any irregular behaviour of the windward wing panel, and so the implication is either that the body load changes radically, or that the wing panel on the leeside undergoes a reversal in load just before reaching the vertical position\*. The rise in pitching moment between  $\lambda = 0$  and 90 degrees implies that this reversed load occurs well aft. Since the control panels are close to the wing. Some insight into the wing behaviour may, therefore, be obtained from the control panel loads. Fig.23 shows that the load reversal near  $\lambda = -90$  degrees, suggested as occurring on the wing, does in fact occur on the control panel for  $\xi_v = 0$  at supersonic speeds though not at M = 0.6.

The rolling moment variation (Fig.22) is also interesting in that at M = 0.6 the zero roll position is stable at all three values of incidence (positive roll produces negative rolling moment). Similarly  $\lambda = 0$  is a stable position at  $\sigma = 12$  degrees at M = 1.4 and 2.0, but is unstable at  $\sigma = 20$  degrees and at 12 and 20 degrees at M = 2.8. The behaviour of the lecside wing panel may again be the explanation, as is shown in the following table where the rolling moments of four control panels are assembled for  $\lambda = 15$  degrees at  $\sigma = 12$  and 20 degrees.

\* Such a reversal has been measured by Spahr<sup>6</sup> on a wing panel of a cruciform wing-body of higher aspect ratio.

|    | Control position $(\lambda)$ | +15                    | +105  | -165  | -75    | C'e   | c <sub>c</sub> |

|    | 2.0                          | <b>-</b> 0 <b>,</b> 12 | +0.04 | +0,08 | -0,03  | -0.03 | -0.1           |
|    | 2.8                          | -0.10                  | +0.03 | +0.06 | -0.01  | -0.02 | +0,05          |
| 20 | 0.6 Ci                       | -0,24                  | +0.05 | +0.11 | -0.06  | -0.14 | -0.8           |
|    | 1•4                          | -0.30                  | +0.10 | +0.18 | +0.10  | +0.08 | +0,2           |
|    | 2.0                          | -0.24                  | +0.09 | +0.14 | +0.04  | +0.03 | +0•5           |
|    | 2.8                          | -0.18                  | +0.07 | +0•13 | +0.01  | +0.03 | +0.4           |

It can be seen that the total rolling moment of the four control panels (with the exception of  $\sigma = 12$  degrees at M = 2.8 where the values are small) is of the same sign as the measured overall rolling moment. Furthermore the total rolling moment is approximately that on the lesside panel.

A monoplane at high incidence is stable in roll at  $\lambda = 0$ . The addition of a windward side wing will be destabilising, and the net result suggested by the table above is of a neutral stability. Thus the sign of the rolling moment may be controlled by the load on the lecside panel, which might have been expected to be the least significant. A complete explanation of the overall behaviour must await the analysis<sup>5</sup> of the experiments on wing panel loads but it seems clear that the wing-vortex interaction is the dominating mechanism, and it would be interesting to study the behaviour over a wide speed range of a shape such as that of Ref.1 where the wings extend to the body apex and the absence of separate body vortices might give a more regular variation.

The other feature of the overall loads which is not discussed subsequently is again the interaction between control planes. The yawing moment curves of Fig.21 show some effect of elevator angle at high incidence at M = 0.6 diminishing with increase of M. The effect is largest when the elevator axis is at about 30 degrees to the vertical.

Except in regions of small panel normal force the panel chordwise centre of pressure (Fig.24) behaves as would be expected almost on an incidence basis only. The spanwise centre of pressure position (Fig.25) shows considerable scatter but there is some consistency, in that, where the normal force reversal occurs ( $\lambda = -60$  and -75 degrees at supersonic speeds) the centre of pressure moves inboard if the load changes sign but moves outboard if the positive load is merely reduced. This implies that the mechanism producing the load reversal affects the inboard part of the control most strongly.

## 5.1 Variation of stabiliser effectiveness with roll angle

The stabiliser effectiveness defined as in Section 4.1 is plotted against roll angle in Fig. 26 where k(p) is derived from panel loads, and k from pitching moment for  $\lambda = 0$  to 45 degrees but from yawing moment for  $\lambda = 45$  to 75 degrees. The use of yawing moment was necessary as the model without tail was not tested at roll angles beyond 45 degrees. Because there may be small zero shifts, the data is less accurate than that in Figs. 10 and 11 and some inconsistencies occur with the data of those figures at  $\lambda = 0$  and 45 degrees. The inconsistencies between the overall results and the panel results may consequently not be genuine especially for  $\lambda > 45$  degrees where the incidence and thus the tail loads become small. The general trends from the panel loads are more reliable and are fairly clear. At M = 0.6 there is little effect of roll angle upon effectiveness with the effectiveness small and increasing slowly with increase of incidence. Effectiveness increases, as noted in Section 4.1 with increase of Mach number and is unaffected by change of roll angle up to about 45 degrees but decreases with roll angle above 45 degrees at higher incidence. The effect is most marked at M = 1.4 where at  $\sigma = 20$  degrees and  $\lambda = 75$  degrees the addition of the tail is actually destabilising. This is because of the load reversal on the leeside panel as shown in Fig. 27 where a single panel only is considered. This figure emphasizes the difference in behaviour of the lecside panel at M = 0.6 and at M supersonic. The constancy of the effectiveness of the complete tail for  $\lambda$  < 45 degrees results because the individual panel effectiveness varies roughly linearly with  $\lambda$  over this range\*.

## 5.2 Variation of elevator effectiveness with roll angle

The elevator effectiveness,  $k_{\eta}$  and  $k_{\eta}(p)$ , as defined in Section 4.2 is plotted against  $\lambda$  in Fig.28. At small incidence,  $\sigma = 5.8$  degrees (Fig.28(a)), there is generally good agreement between  $k_{\eta}(p)$  and  $k_{\eta}$  and the effectiveness is little dependent upon  $\lambda$ . However at higher incidence (Figs.28(b) and (c)) the agreement between the two derivations of effectiveness declines and the - 32

<sup>\*</sup> It might be remarked that there is a distinction between the variation of effectiveness with  $\lambda$  in Fig.26 at constant total incidence  $\sigma$  and comparison of Figs.10 and 11 in which  $\alpha$  is taken as the variable.

variation with  $\lambda$  increases. The general shape of the pairs of curves is similar with the  $k_{\eta}$  (from pitching moment) apparently an exaggeration of  $k_{\eta}(p)$  (from panel load). Of course this is not unexpected since the simple carryover factors assumed cannot apply to conditions in which one panel of a pair carries several times the load of the other one, as Fig.30 shows to be the case. Also where strong vortex interactions are involved enange of elevator angle may change the local flow pattern and so change the basic body loading.

The wide variation of elevator effectiveness with roll angle and Mach number is clearly an undesirable feature of the present configuration and if high incidence is to be used to take advantage of non-linear lift other forms of control need to be sought.

## 5.3 Aileron effectiveness

In a similar way to elevator effectiveness alleron effectiveness,  $k_{\zeta}(p)$ , has been defined as the ratio of change in rolling moment due to change in aileron angle from 0 to 10, 20 and 30 degrees to the change given by a simple estimate. The estimate (Table 5) makes the same assumptions as for elevators and additionally that the spanwise centre of pressure is at half the panel span. The measured aileron torque has been obtained by summing the rolling moment due to deflection of the live panel at intervals of 90 degrees in  $\lambda$ . The results are shown in Fig.29. Despite the large variations of the individual panel effectiveness (shown in Fig.30), the four panels have an almost constant effectiveness. For 10 degrees alleron angle values range from 0.6 at M = 1.4and low incidence, to about 0.85 at M = 2.8 and  $\sigma = 20$  degrees. There is always a reduction in effectiveness with increase of alleron angle above 10 degrees.

To put the aileron power into perspective the rolling moment obtainable from 10 degrees control deflection is compared below with the total rolling moment measured at  $\sigma = 20$  degrees and  $\lambda = 15$  degrees

M = 0.6 = 1.4 = 2.0 = 2.8  $\Delta C_{\ell} = 10^{\circ} = 0.67 = 0.60 = 0.40 = 0.32$   $C_{\ell} = -0.9 = +0.2 = +0.5 = +0.3$ 

Though the model is not intended to be of a practical design the figures show that controls of the size used would be barely adequate for roll control.

The final figure (30) shows the rolling effectiveness of a single panel for 10 degrees control angle. Though no pretence is made that this figure is understood some comment is offered. The first point is that as  $\xi_{u}$  tends to zero the curves of Fig. 30 should be symmetrical about  $\lambda = \pm 90$ , i.e. a vertical plane of symmetry. That this is not quite so for  $\xi_v = 10$  degrees shows that the curves cannot be regarded solely as a measure of local flow conditions. However, the main features can probably be referred to the local flow. At  $\sigma = 6$  degrees the tail region is probably free of vortices and there is little variation of effectiveness with  $\lambda$  though the maximum occurring at  $\lambda = -90$  degrees as well as at  $\lambda = +90$  degrees scems inexplicable. As  $\sigma$ increases the effect of wing and body vortices becomes stronger and at M = 2.8 the panel on the lesside ( $\lambda = -90$  degrees) is almost completely ineffective. As well as the low kinetic pressure which may result in this region from viscous losses in the vortices and from the high Mach number on the leeside of the wing, there may also be interference from the wing trailing shock. In contrast the panel at  $\lambda = +90$  degrees could be in a flow of reduced Mach number and high kinetic pressure as shown in Fig. 15. The opposite behaviour as might be expected from changes in kinetic pressure is shown for M = 0.6.

Finally it might be noted that there is remarkable similarity between the curve for M = 2.8 at  $\sigma = 20$  degrees and that of Fig. 31 of Ref.1 at M = 4.3.

## 6 CONCLUSIONS

The essential flow feature for a slender missile of the type tested is the development at high incidence of coiled vortex sheets springing from the leading edges, giving rise, advantageously, to large non-linear contributions to lift. The tests show that, the rear controls mounted closely behind the wing trailing edges, have some undesirable characteristics which are at least partially attributable to the vortex fields in which they operate. For this type of configuration other forms of controls should be sought. The main findings are summarised below.

At zero control angle the stabiliser effectiveness is small at M = 0.6but increases with increase of Mach number. A flow survey shows that the flow in the region of the controls at 20 degrees incidence at M = 2.8 can be qualitatively related to a two-dimensional flow at the wing trailing edge. Nevertheless, there exists a simple correlation between effectiveness and wing lift at an incidence of 20 degrees over the Mach number range of the tests.

2 Stabiliser effectiveness is strongly dependent upon roll angle reducing rapidly for values above 45 degrees and reaching negative values at high incidence at supersonic speeds.

3 Elevator effectiveness is fairly constant over the Mach number range at zero roll angle but varies asymmetrically with incidence, being greater at large negative incidence for positive control angles than at positive incidence,

4 Elevator effectiveness is strongly dependent upon roll angle at large incidence.

5 Ailcron effectiveness for four panels is fairly constant with incidence, roll, and Mach number but a single panel exhibits variations from zero to 1.5 between  $\lambda = -90$  and +90 degrees at M = 2.8.

6 The rolling moment variation with roll angle on the complete model changes from being stable when one pair of wings is horizontal for all incidences at subsonic speeds and for low incidence at supersonic speeds, to being unstable for high incidence at supersonic speed. It is suggested that this effect may arise mainly from the interaction of the body vortices and of the vortices from the near horizontal wings with the wing on the leeside of the body.

## SYMBOLS

- x, y, z right-handed Cartesian coordinates in axes fixed in the model with x positive forwards along the body axis, y to starboard and z downwards with origin distant 4d forward of the wing trailing edge
  - x, y', z' coordinates in axes rotated through an angle  $-\lambda$  about the x axis relative to x, y, z

$$x'_p, y'_p, z'_p$$
 coordinates in axes rotated about the  $y_p$  axis so that  $x'_p$  and  $x'_p$  axes are coincident

Force and moment coefficients on whole model in axes x, y, z and using  $S_B$  as reference area and d as reference length.

| -° <sub>x</sub> | axial force     |
|-----------------|-----------------|
| °y              | sideforce       |
| -°z             | normal force    |
| °e              | rolling moment  |
| C <sub>m</sub>  | pitching moment |
| C <sub>n</sub>  | yawing moment   |

| The wings are of delta planform, with aspect ratio of exposed pairs of panels $0.31$ , and total span of 2.5 times the diameter of the body, which is of fineness ratio 19. The rectangular controls, of span equal to that of the wings, and chord $0.5$ times the body diameter, are mounted with a half chord gap to the wing trailing edge. Loads are measured on one control in addition to overall loads. The tests cover an incidence range up to $\mathbb{Z}$ degrees for 0 and $45$ degrees roll and a complete roll range for | The wings are of delta planform, with aspect ratio of exposed pairs of<br>penels 0.31, and total span of 2.5 times the diameter of the body, which<br>is of fineness ratio 19. incidences of 6, 12 and 20 degrees with elevator angles of 0, 10, 20 and 30 degrees. A brief survey of the flow in the region of the tall at M = 2.8 at an incidence of 20 degrees is included.

The results show that there are large variations with roll angle in both stabiliser effectiveness in pitch and elevator effectiveness. Alleron effectiveness is fairly constant. The rolling moment variation with roll angle on the complete model changes from being stable when one pair of wings is horizontal for all incidences at subsonic speeds and for lor incidence at supersonic speeds, to being unstable for high incidence at supersonic speed. It is suggested that this effect may arise mainly from the interaction of the body vortices and of the vortices from the near horizontal wings with the wing on the leeside of the body.

incidences of 6, 12 and 20 degrees with elevator angles of 0, 10, 20 and 30 degrees. A brief survey of the flow in the region of the tail at M = 2.8 at an incidence of 20 degrees is included.

The results ahow that there are large variations with roll angle in both stabiliser effectiveness in pitch and elevator effectiveness. Alleron effectiveness is fairly constant. The rolling moment variation with roll angle on the complete model changes from being stable when one pair of wings is horizontal for all incidences at subsomic speeds and for lon incidence at supersomic speeds, to being unstable for high incidence at supersomic speed. It is suggested that this effect may arise mainly from the interaction of the body vortices and of the vortices from the near horizontal wings with the wing on the leeside of the body.

incidences of 6, 12 and 20 degrees with alevator angles of 0, 10, 20 and 30 degrees. A brief survey of the flow in the region of the tail at M = 2.8 at an incidence of 20 degrees is included.

The results show that there are large variations with roll angle in both stabiliser effectiveness in pitch and elevator effectiveness. Ailerom effectiveness is fairly constant. The rolling moment variation with roll angle on the complete model changes from being stable when one pair of wings is horizontal for all incidences at subsomic speeds and for loc incidence at supersonic speeds, to being unstable for high incidence at supersonic speed. It is suggested that this effect may arise mainly from the interaction of the body vortices and of the vortices from the near horizontal wings with the wing on the leeside of the body.
